Inertia beta: product overview

Oct 15, 2026 · @Kyle Christmon

Summary

Inertia is an agentic layer that keeps FWTX DAO moving between Wednesday meetings: it captures ideas from everywhere the DAO talks, organizes them under the initiatives members have voted on, and helps members claim work and get credit.

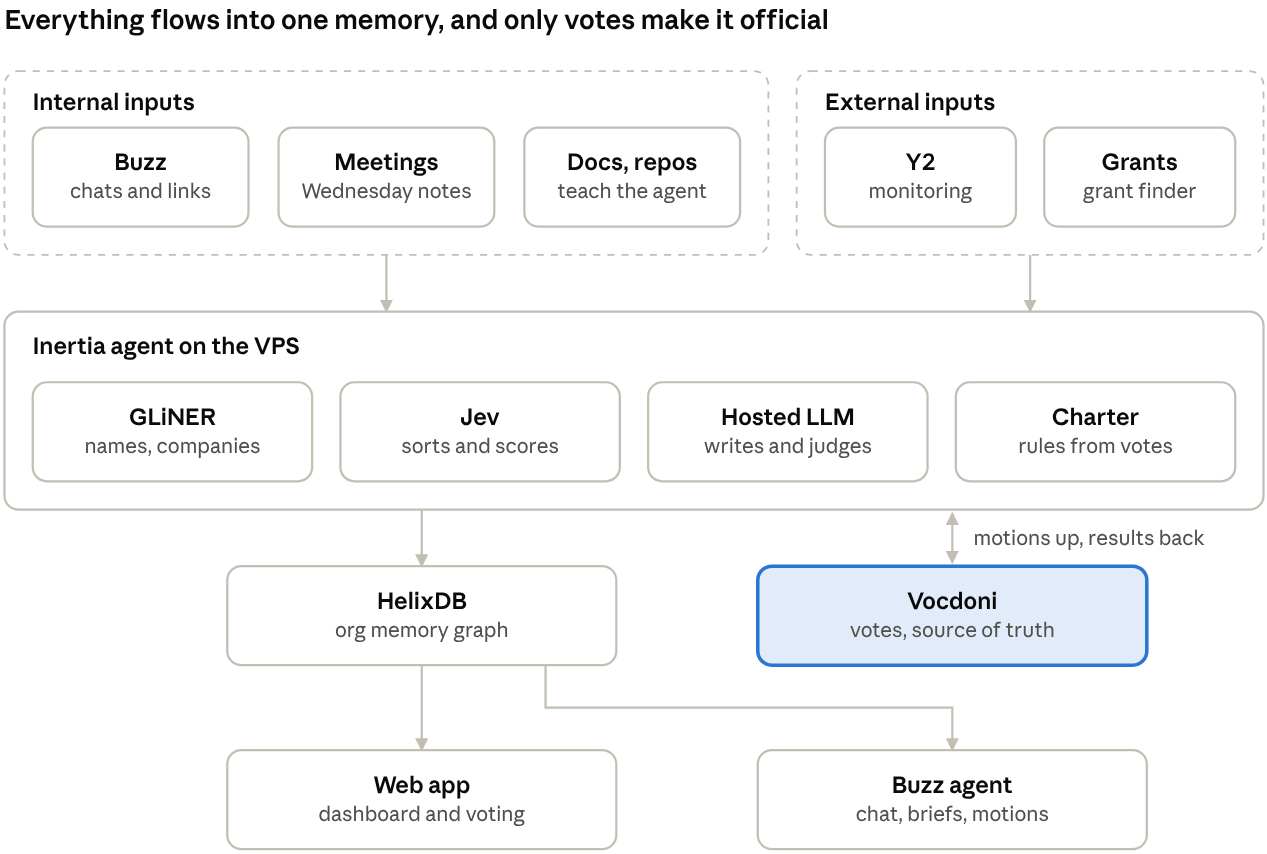

FWTX is strong publicly (events, social, growth over three years) but thin on internal execution. Members aren't voting enough, collaboration on projects is uneven, and the bounty board goes underused. Ideas surface in meetings and chats, then die because no one carries them forward.

The beta is scoped to FWTX only, used as the test bed. The longer-term vision is an open-source operating layer any DAO or guild can plug into.

Three principles hold throughout:

- **Governance is the source of truth.** Ratified votes and the constitution define what the DAO works toward. The agent proposes and organizes, but never overrides a vote.
- **Transparent, not surveillance.** Members can see what the agent reads, what it learned, and why it ranked something first.
- **Members own the upside.** Freed-up time flows back to members as new projects and credit, not cuts.

How it works

Inertia system design · inputs, agent, memory, governance, outputs

Inputs come from inside the DAO (Buzz, Wednesday meetings, docs and repos) and outside it (Y2 and the grant finder). The agent processes them in three passes, files the results in HelixDB, and serves them through the web app and Buzz. Vocdoni is the only place anything becomes official.

External monitoring runs as a loop. The agent builds a hotlist from active initiatives and projects, tells Y2 what to watch, and Y2 reports back only what could change a decision, timeline, or cost. Each hotlist topic shows which initiative it serves and retires when that work closes.

The weekly rhythm. Wednesday's meeting is processed into memory. During the week, members claim work in the web app and talk in Buzz, while Y2 and the grant finder watch the outside world. Before the next Wednesday, the agent sends one brief: what was committed, what moved, what's stuck, what changed outside, and any motions ready for a vote.

Where people reach the agent. In Buzz for day-to-day questions, work requests, and links. In the web app for the big picture, claiming work, and voting. Both talk to the same agent and the same memory.

Components

Each piece has one job, and the expensive model gets called the least.

Component	Role in Inertia	Where it runs
Buzz agent	Main front door: answers questions, takes work requests and links, posts the weekly brief and drafted motions	Joins the FWTX Buzz workspace as a member via Buzz's agent harness
Web app	Dashboard: initiatives, projects, open loops, weekly brief, hotlist, credit, votes; plus sharing and a chat box to the same agent	VPS or Vercel
HelixDB	Org memory graph: people, ideas, initiatives, companies, meetings, and the links between them	VPS
GLiNER	Pulls names, companies, places, and projects out of text	VPS (CPU is fine)
Jev (TypeSafe AI)	Fast typed decisions with confidence: what an item is, which initiative it belongs to, whether an alert is worth sending	Hosted API
Hosted LLM	Writing and judgment: weekly brief, motions, prioritization	Hosted API (GLM if plan terms allow)
Charter	Ratified rules the agent follows: priorities, and what it may do alone, propose, or leave to a vote	Stored with the agent; amended by vote
Vocdoni	Voting and the record of what the DAO has agreed to	FWTX's existing Vocdoni setup

Component	Role in Inertia	Where it runs
Y2	External monitoring against an agent-maintained hotlist tied to active work	Hosted (run by an FWTX founder)
Grant finder	First external signal: grants matched to initiatives	Member-built tool

Identity runs on Nostr keys. Buzz already signs every message with a member's key, so the web app can use the same key for login, and credit rolls up to one identity everywhere.

The agent's confidence drives its permission tiers. High-confidence, low-stakes actions (tagging, linking) happen automatically. Lower confidence or higher stakes (new projects, credit) go to a human. New initiatives, spending, and charter changes always go to a vote.

What we already have

Resource	Notes
Spare VPS	No GPU, so model calls go to hosted providers. Hosts the agent, HelixDB, and scheduled jobs
GLM coding subscription	For building the code; runtime use depends on plan terms
Next.js, Supabase, TypeScript, Vercel experience	Fastest path for the web app
FWTX Buzz workspace	Members being moved onto it now; adoption still early
Vocdoni governance platform	Already in use by FWTX
Y2	Run by an FWTX founder; API, MCP server, webhooks
Grant finder	Built by a DAO member
Wednesday meeting notes and recordings	Test data for extraction; to be submitted

Resource	Notes
Brainstorm notes	Original Inertia concept

Resources we still need

- [ ] **LLM API access and a budget** for the agent's reasoning and writing, with a monthly spending cap. GLM if the coding plan allows runtime use; otherwise a pay-per-use provider.
- [ ] **Jev early access** from TypeSafe AI (currently waitlisted).
- [ ] **Y2 API key** and a workspace for the hotlist and webhooks.
- [ ] **Grant finder access**: an API, export, or feed the agent can read.
- [ ] **A Buzz agent identity**: keys and permissions for the agent to join the FWTX workspace.
- [ ] **Vocdoni integration details**: API access and how FWTX's current process is set up.
- [ ] **Transcription**: use existing transcripts, or a speech-to-text API for recordings.
- [ ] **A draft charter** for members to review and ratify.
- [ ] **Two or three past Wednesday meetings** (notes plus recordings) as the first test set.
- [ ] **A domain** for the web app.

Open questions and conflicts

None of these block starting, but each should be settled before the piece it touches gets built.

Area	Question or conflict	Why it matters
Sovereignty vs. hosted tools	The LLM, Jev, and Y2 are hosted, so DAO content leaves our servers	Conflicts with the digital sovereignty ethos. State it plainly in the charter; keep each provider swappable
GLM plan terms	Does the coding subscription allow use as the agent's runtime model?	If not, budget for a separate API

Area	Question or conflict	Why it matters
Jev	How long is the waitlist? Can it pull open-ended names, or only choose from set options?	Decides whether Jev replaces or complements GLiNER, and the fallback if access is slow
HelixDB	Maturity, hosting on our VPS, query language, backups	It's young; confirm in week one before building on it. Fallback is Postgres with pgvector
Login and data store	Can HelixDB be the only store, with Nostr login, or do we still need Postgres for users and votes?	Two databases doubles the plumbing
Vocdoni	Is FWTX's on-chain record Vocdoni, or another chain? Is there an API for creating and reading votes?	Must stay one clear record of what the DAO agreed to. Placeholder until confirmed
Robert's Rules	Vocdoni runs ballots, not procedure	The agent acts as parliamentarian (motion, second, amendments, vote). Needs a simple procedure spec in the charter
Voting weight	Credit points giving voting weight, and whether Vocdoni supports it	Affects how credit and governance connect
Buzz	Early-stage and changing fast; adoption at FWTX is still aspirational	Build as an agent, not a fork. If members aren't on Buzz, the agent needs another way in
Web app vs. Buzz discussion	Chat in both places could split the DAO's attention	Same agent and memory behind both; web app threads link to Buzz threads
Identity	Matching Buzz keys, outside names, and voices in recordings to one person	Credit depends on it. Members link accounts to one Nostr key
Privacy and consent	Which channels the agent may read; how members see and correct what it learned	Core to trust; opt-in by channel

Area	Question or conflict	Why it matters
Y2 scope	Can profiles be tuned to local, niche signals (DFW grants, venues, city programs)?	Its strength looks global; test early

Beta plan

The beta runs about four weeks and ends with one live Wednesday cycle. The success metric: more tasks claimed and finished between Wednesdays than before.

1. **Week 1: memory and extraction.** Set up HelixDB on the VPS and confirm it fits. Process two or three past Wednesday meetings into initiatives, projects, names, and open loops. Check the results by hand. Draft the charter.
2. **Week 2: dashboard.** Web app reading from HelixDB, with Nostr login. Initiatives, projects, open loops, claiming, and credit.
3. **Week 3: Buzz agent and first external signal.** Agent joins the FWTX Buzz workspace. Connect the grant finder and demo the full loop: grant appears, agent links it to an initiative, drafts a motion for Wednesday.
4. **Week 4: live cycle.** Run a real Wednesday-to-Wednesday cycle. First weekly brief goes out before the meeting. Measure claims and completions.

Deferred until the core loop works: Y2 hotlist monitoring, full Vocdoni integration, Jev (if access is still pending), video and social feeds, and the member credit page.

Division of work between partners: to decide.
